MTS 1500
Automated melt treatment station
What is the MTS 1500?

The MTS 1500 is an automated melt treatment station that:

+ Provides a platform to perform all necessary melt treatments in a single operation
+ Improves efficiency of the various treatments
+ Reduces operator involvement
+ Reduces emissions

A new perspective on performance

The MTS 1500 is based upon FDU rotary degassing technology, with the additional capability of adding a range of melt treatment products.

The addition of these treatment products uses a unique method, whereby the fluxes are fed from a dispensing unit into a vortex deliberately created by the spinning rotor. This vortex is carefully controlled to ensure a very efficient mixing of the treatment products.
The standard treatment cycle using the MTS 1500 consists of a series of stages that can be summarised as follows:

1. **Consumables introduction**
   Shaft, rotor and baffle plate are first lowered into the melt.

2. **Vortex formation**
   The baffle plate is deactivated and rotor speed is increased to a point at which a vortex is created around the shaft.

3. **Addition of treatment agents**
   The required amount of flux is then dispensed directly into the vortex and drawn down into the melt.

4. **Vortex termination and degassing**
   After the flux addition the baffle plate is activated again to terminate the vortex and initiate the degassing phase.
XSR and FDR rotors
New designs of rotors that
+ create the optimum vortex for the addition of the treatment products
+ are highly efficient in removing dissolved hydrogen

COVERAL* MTS fluxes
A range of new treatment agents has been specifically formulated for use with the MTS 1500 that
+ covers the principal foundry operations of cleaning, drossing, modification and grain refinement
+ keeps smoke and fume to a minimum

Benefits of the MTS 1500
The MTS 1500 offers the foundry several benefits that can be divided into four main categories

Metallurgical benefits
The highly efficient manner in which the melt treatment products are introduced gives a number of metallurgical benefits in the finished casting:

+ Consistent mechanical and physical properties
+ Homogeneous microstructure and composition
+ Very good levels of metal cleanliness
+ Controlled gas porosity

Environmental benefits
The MTS 1500 assists the foundry in achieving a better environmental performance by

+ using less consumables (flux, inert gas)
+ reducing the amount of dross produced
+ reducing emissions
+ reducing treatment time and melt superheat with associated energy savings

Health and Safety benefits
The MTS 1500 contributes to the foundry Health & Safety improvements:
A healthier environment through reduced particulate and gaseous emissions compared to conventional treatments because

+ the MTS 1500 uses less flux
+ the action of the vortex draws the flux down into the melt where it is quickly mixed into the metal
+ the flux used for the melt treatment is fully consumed and does not continue to react post treatment
+ a safer environment through reduced operator involvement in the melt treatment process

Economic benefits
Of major importance to aluminium foundries is reducing process costs. From this perspective the MTS 1500 brings value to the foundry by

+ reducing treatment costs
  - reduced inert gas consumption
  - reduced flux consumption
  - reducing aluminium loss in the dross
  - reduced labour costs
+ improving performance
  - fast melt turn around
  - reproducible melt quality
  - increased reliability and decreased maintenance
Case study A

The foundry
A German sand foundry produces small and medium batch series using an automatic moulding line.

Foundry practice
Foundry A melts various alloys in an induction furnace followed by FDU rotary degassing in a transfer ladle using MTS 1500 technology. COVERAL MTS 1572 for sodium modification and COVERAL MTS 1582 for grain refining is added depending on alloy and casting type.
The specification for sodium in melt is 40 to 90 ppm measured by spectrometer; 9 percent (23 out of 260 batches) were out of sodium specification.

Foundry requirements
Foundry wants to improve sodium yield in a stable process to avoid after treatment:

+ Reduced number of batches out of specification
+ Weight controlled addition of sodium modifier
+ Production process without stoppage
+ Stable melt treatment
+ Increased productivity

Achievements
The use of a load cell results in a more stable process with a weight difference below 5 percent based on a 500 g COVERAL MTS 1572 target addition rate. Finally less than 1 percent (2 out of 260 batches) are out of sodium specification only.
Productivity has increased due to a trouble-free treatment and process tracebility improves quality management.
Case study B

The foundry
Foundry B produces a range of castings in both high pressure and low pressure.

Foundry practice
Foundry B melts centrally and then transfers metal to the casting furnaces using a transfer ladle. Melt treatment was carried out in the transfer ladle using a rotary degassing unit with a manual addition of flux. MTS machine is required.

Foundry requirements
The foundry wanted to expand its activity by a factor of four and needed a second machine to increase melt treatment capacity. The metal content in dross is high, to reduce the melt loss and save energy, an MTS machine is required. Achievements
The high efficiency of the MTS 1500 has given significant cost savings in terms of reduced treatment costs and a reduction in metal loss in the dross. More consistent process due to fully automated device and about 60 tons less aluminium loss per year.

Case study C

The foundry
A European wheel foundry produces aluminium wheels in low-pressure die casting.

Foundry practice
Foundry C uses AlSi7Mg alloy, molten in a tower smelter and treated in an INSURAL* transfer ladle. The original practice was a manual addition of TiBor rods followed by a FDU rotary degassing treatment.

Foundry requirements
The foundry wants to do all necessary treatment steps in a single operation to reduce operator involvement in TiBor rods addition. Moreover they recognised the high metal content in dross and asked for a reduction in aluminium loss.

Achievements
The titanium-boron based COVERAL MTS 1582 grain refiner has been introduced and is applied through a MTS 1500 device. An amount of 250 g COVERAL MTS 1582 grain refiner is added into a carefully controlled vortex during each MTS treatment. It results in an excellent grain refining effect at lower addition rates compared to TiBor rods; the grain refining level is more constant now due to the automated process. The resulting dross is low in metal and the foundry reports reduced effort in cleaning the LPDC furnaces.
